

Revision Delay Alarm

Note: An automated Alarm for this check is in use. Updates will be seen here ([CloudWatch Alarm Automation](#))

Step-By-Step instructions:

1. Log in to AWS Polarion production account
2. Go to EC2 service, and select the ec2 instance "prod."
3. Click on connect and choose Session Manager.

4. Run below commands to verify SVN backup status:
sudo su
docker ps
docker exec -it<container-id>/bin/bash
Run repository revision comparison script
cd bin
./svn-repo-status.sh (this will give the revision number)

Output:

```
[2021-05-15 14:28:45+00:00]: Info: ./svn-repo-status.sh - 0 revision delay: hotcopy status acceptable - SRC:1514266 BU:1514266
```

Check PROD Backup EFS integrity SVN Revision delay

1. Log in to CloudWatch , Click on insights and select the polarion-backup.log for the Production server.

2. Filter for the following string "svn-repo-status.sh.*revision delay" and Set time to last 30 minutes

```
fields @timestamp, @message  
| filter @message like /svn-repo-status.sh.*revision delay/  
| sort @timestamp desc  
| limit 20
```

- At 50% of the results are to be acceptable overall – otherwise we need to check backup performance (via ticket)
- If all the latest 30% were not acceptable and number increases – we have to check the EFS backup procedure urgently (+ticket) (recovery team needs to be trained for this).

Acceptance Criteria:

If there are less than **150** revision delays in the above output and there is no "WARN" in the output, the check is fine. Else, contact the recovery team member on duty for help!
As of June/2021 there is a backup performance on prod system: there are peaks with high delays in SVN gap. (up to ~1200. Please inform Michael Baunach via teams chat (no calls please) if it is even higher
we expect the situation to return to normal again after the next redeployment of prod-system
